Foundation Vision-Language Models for Visual Brain Encoding

Assignment 3.2

Cognitive Science and Artificial Intelligence

Subject 6 -- Algonauts 2023 Dataset

VLMs: CLIP ViT-L/14 | BLIP-2 OPT-2.7B

ROIs: prf-visualrois (V1-hV4) | floc-bodies (EBA, FBA, mTL)

Encoding: Ridge / Banded Ridge | Metric: Pearson r (3-fold CV)

VLM-Based Encoding Models for Visual ROIs

Aim

Move beyond CNN-only encoders by evaluating whether foundation vision-language models (VLMs) and LLM-derived semantic representations better explain responses in Visual ROI-specific brain responses (vertices), while retaining performance in early retinotopic areas.

ROI Sets Covered:

- **Early retinotopic visual regions (prf-visualrois):** V1v, V1d, V2v, V2d, V3v, V3d, hV4
- **Body-selective regions (floc-bodies):** EBA, FBA-1, FBA-2, mTL-bodies

Pipeline:

1. Model Selection (Reproducibility First)
2. Visual Feature Extraction (Token-Aware: global + patch-level with mean pooling)
3. LLM-Semantic Feature Construction (Captioning with multiple prompts + text embedding)
4. Encoding Models (Visual-only, Semantic-only, Joint visual+semantic with banded ridge)
5. Prompt / Instruction Ablation (Object-centric vs. Scene-centric vs. Reading-centric)
6. Evaluation & Comparison against CNN baseline

Task 1: Model Selection & Environment Setup

Selected VLMs

Property	VLM 1: CLIP ViT-L/14	VLM 2: BLIP-2 (OPT-2.7B)
Checkpoint	`openai/clip-vit-large-patch14`	`Salesforce/blip2-opt-2.7b`
Vision Backbone	ViT-L/14 (24 layers, 1024-d)	ViT-G/14 via EVA-CLIP (Q-Former bridge)
Input Resolution	224 x 224	224 x 224
Instruction-Tuned	No (contrastive pre-training)	Yes (bootstrapped from frozen LLM)
Architecture Type	Dual encoder (contrastive)	Instruction-tuned multimodal (generative)
Text Encoder	Transformer (12 layers, 768-d output)	OPT-2.7B decoder LLM

Justification:

- **CLIP** is the canonical contrastive VLM, providing aligned visual-textual embeddings in a shared space. Its dual-encoder design allows independent extraction of both visual and text features.
- **BLIP-2** is an instruction-tuned generative VLM that bridges a frozen vision encoder with a frozen LLM via a lightweight Q-Former. It generates rich textual descriptions and can also provide visual embeddings from its vision encoder, offering a complementary architecture to CLIP.

Subtask:

Install necessary libraries and initialize both models.

Code Cell 1

```
!nvidia-smi
```

Output:

```

Task 2: Visual Feature Extraction (Token-Aware)

Strategy

For each VLM's vision encoder we extract **two** representations:

Representation	**CLIP ViT-L/14**	**BLIP-2 (EVA-CLIP -> Q-Former)**
(a) Global embedding	CLS token -> visual projection (768-d)	Q-Former query output, mean-pooled (768-d)
(b) Token-level (patch)	Mean-pool over 256 patch tokens (1024-d)	Mean-pool over Q-Former query tokens (768-d)

Pooling Justification: We use **mean pooling** over patch/query tokens because it captures the average spatial information across the entire image without introducing additional learned parameters, providing a stable and reproducible representation that complements the CLS/global embedding which may over-emphasize salient regions.

Subtask:

Extract global and mean-pooled patch features from both CLIP and BLIP-2 vision encoders for all training images.

Reasoning:

I will process all training images in batches through both CLIP and BLIP-2 vision encoders. For CLIP: (a) global = CLS via `visual_projection(pooler_output)`, (b) patch = mean over `last_hidden_state[:, 1:, :]` then project. For BLIP-2: I use the Q-Former's output queries -- (a) global = mean over all 32 query tokens, (b) since Q-Former already aggregates patches via cross-attention, I also take per-token representations and mean-pool. Both provide complementary spatial summaries.

Code Cell 4

```
import os, numpy as np

# -- CHECKPOINT: skip if visual features already saved --
_ckpt_vis = '/kaggle/working/ckpt_vlm_visual.npz'
if os.path.exists(_ckpt_vis):
    _d = np.load(_ckpt_vis)
    vlm_visual = {k: _d[k] for k in _d.files}
    print(f"Loaded vlm_visual from checkpoint: {list(vlm_visual.keys())}")
    for k, v in vlm_visual.items():
        print(f"  {k:20s} shape: {v.shape}")
else:
    from PIL import Image
    from torch.utils.data import DataLoader, Dataset
    from tqdm import tqdm

    class ImageListDataset(Dataset):
        def __init__(self, paths):
            self.paths = paths
        def __len__(self):
            return len(self.paths)
        def __getitem__(self, idx):
            return Image.open(self.paths[idx]).convert('RGB')

    img_dataset = ImageListDataset(training_image_files)
    img_loader  = DataLoader(img_dataset, batch_size=8, shuffle=False,
                             collate_fn=lambda x: x)

    # -- Storage --
    clip_global_list, clip_patch_list = [], []
    blip2_global_list, blip2_patch_list = [], []

    print("Extracting visual features from CLIP and BLIP-2 vision encoders...")
    with torch.no_grad():
        for batch_imgs in tqdm(img_loader, desc="Visual features"):

            # -------- CLIP --------
            clip_inputs = clip_processor(images=batch_imgs, return_tensors="pt").to(device)
            vision_out  = clip_model.vision_model(**clip_inputs)

            # (a) Global: CLS -> projection  (batch, 768)
            global_feat = clip_model.visual_projection(vision_out.pooler_output)
            clip_global_list.append(global_feat.cpu().numpy())

            # (b) Patch mean: mean over patch tokens -> projection  (batch, 768)
            patch_tokens = vision_out.last_hidden_state[:, 1:, :]   # drop CLS
            patch_mean   = patch_tokens.mean(dim=1)
            patch_feat   = clip_model.visual_projection(patch_mean)
            clip_patch_list.append(patch_feat.cpu().numpy())

            # -------- BLIP-2 vision encoder + Q-Former --------

Visual feature extraction complete.
Saved vlm_visual to /kaggle/working/ckpt_vlm_visual.npz
```

Task 3: LLM-Semantic Feature Construction

Captioning / Description Strategy

For each training image, generate text descriptions using **BLIP-2** (instruction-tuned generative VLM) with **three prompt conditions**:

Prompt ID	Prompt Text (exact)	Focus
Object-centric	`"Question: Describe the objects and their attribu	Objects, parts, colors, shapes
Scene-centric	`"Question: Describe the place, scene layout, and	Scene category, layout, depth
Reading-centric	`"Question: Transcribe and describe any visible	OCR-like, text content

Text Embedding Strategy

Embed each caption using the **CLIP text encoder** (same checkpoint: `openai/clip-vit-large-patch14`), yielding a 768-d text embedding per caption. This ensures visual and text embeddings live in the **same aligned feature space**, enabling meaningful joint models and direct comparisons.

Subtask:

Generate captions for all training images with all three prompts, then embed them using CLIP's text encoder.

Reasoning:

I will iterate through all training images in batches, generating captions with BLIP-2 for each of the three prompts. This is the most time-consuming step. I'll store the raw caption strings, then embed them all using CLIP's text encoder in a subsequent cell.

Code Cell 5

```
import os, json

# -- CHECKPOINT: skip if captions already saved --
_ckpt_cap = '/kaggle/working/ckpt_captions.json'
if os.path.exists(_ckpt_cap):
    with open(_ckpt_cap) as f:
        captions = json.load(f)
    print(f"Loaded captions from checkpoint: {list(captions.keys())}")
    for k in captions:
        print(f"  {k}: {len(captions[k])} captions")
else:
    # -- Exact prompts used for each condition --
    PROMPTS = {
        'object':  "Question: Describe the objects and their attributes in this image. Answer:",
        'scene':   "Question: Describe the place, scene layout, and spatial context of this image. Answer:",
        'reading': "Question: Transcribe and describe any visible text or writing in this image. Answer:",
    }

    # Storage for raw captions
```

```
captions = {k: [] for k in PROMPTS}

print("Generating captions with BLIP-2 (3 prompts x all images)...")
print("This will take a while -- ~3 passes over the dataset.\n")

with torch.no_grad():
    for prompt_key, prompt_text in PROMPTS.items():
        print(f"  Prompt: '{prompt_key}' ...")
        for batch_imgs in tqdm(img_loader, desc=f"  {prompt_key}"):
            blip_inputs = blip2_processor(
                images=batch_imgs,
                text=[prompt_text] * len(batch_imgs),
                return_tensors="pt"
            ).to(device, torch.float16)

            generated_ids = blip2_model.generate(**blip_inputs, max_new_tokens=50)
            decoded = blip2_processor.batch_decode(generated_ids, skip_special_tokens=True)
            captions[prompt_key].extend(decoded)

        print(f"    Generated {len(captions[prompt_key])} captions.")

# Verify
for k in captions:
    print(f"\n[{k}] Sample caption: {captions[k][0][:120]}...")
print(f"\nCaption generation complete. {len(captions['object'])} captions per prompt.")

# -- CHECKPOINT: save captions --
with open(_ckpt_cap, 'w') as f:
    json.dump(captions, f)
print("Saved captions to /kaggle/working/ckpt_captions.json")
```

Output:

```
Generating captions with BLIP-2 (3 prompts x all images)...
This will take a while -- ~3 passes over the dataset.

  Prompt: 'object' ...
```

Output:

```
  object: 100%|##########| 1136/1136 [21:33<00:00,  1.14s/it]
```

Output:

```
    Generated 9082 captions.
  Prompt: 'scene' ...
```

Output:

```
  scene: 100%|##########| 1136/1136 [17:33<00:00,  1.08it/s]
```

Output:

```
    Generated 9082 captions.
  Prompt: 'reading' ...
```

Output:

```
  reading: 100%|##########| 1136/1136 [17:19<00:00,  1.09it/s]
```

Output:

```
    Generated 9082 captions.
```

```
[object] Sample caption: Question: Describe the objects and their attributes in this image. Answer: A baseball player
...

[scene] Sample caption: Question: Describe the place, scene layout, and spatial context of this image. Answer: A baseball fiel
...

[reading] Sample caption: Question: Transcribe and describe any visible text or writing in this image. Answer: The batter is h

Caption generation complete. 9082 captions per prompt.
Saved captions to /kaggle/working/ckpt_captions.json
```

Reasoning:

Now I will embed the generated captions using CLIP's text encoder. The `get_text_features` method returns the projected 768-d embedding directly. I process in batches to keep memory manageable.

Code Cell 6

```
import os, json, numpy as np

# -- CHECKPOINT: skip if text embeddings already saved --
_ckpt_te = '/kaggle/working/ckpt_text_embeddings.npz'
if os.path.exists(_ckpt_te):
    _d = np.load(_ckpt_te)
    text_embeddings = {k: _d[k] for k in _d.files}
    print(f"Loaded text_embeddings from checkpoint: {list(text_embeddings.keys())}")
    for k, v in text_embeddings.items():
        print(f"  {k} shape: {v.shape}")
else:

Task 4: Encoding Models (Multi-Feature-Space)

Encoding Model Setup

For each ROI (same 10-vertex protocol) we train encoding models under **four conditions per VLM**:

Condition	Features	Regression
(A) Visual-only	Concat(global, patch_mean) from VLM vision encoder	Ridge
(B) Semantic-only (Object)	CLIP text embedding of object-centric captions	Ridge
(C) Semantic-only (Scene)	CLIP text embedding of scene-centric captions	Ridge
(D) Joint visual+semantic	Visual features + Object-centric semantic features	**Banded Ridge** (separate alpha per feature space

Banded Ridge Regression (from `himalaya`) applies separate L2 regularisation per feature group, preventing the higher-dimensional visual features from dominating the joint model.

Subtask:

Prepare feature matrices, train Ridge and Banded Ridge models for both ROI sets, and collect predictions.

Reasoning:

I will: (1) Assemble the feature matrices for each condition; (2) For the joint model, use `himalaya.ridge.GroupRidgeCV` (banded ridge) with the visual and semantic features as separate groups; (3) Train per-ROI models for both prf-visualrois and floc-bodies ROI sets; (4) Use 5-fold cross-validation for alpha selection in banded ridge; (5) Store Pearson correlations for later comparison.

Code Cell 7

```
from sklearn.linear_model import RidgeCV
from sklearn.model_selection import KFold
from scipy.stats import pearsonr
import numpy as np, os

# -- CHECKPOINT: load visual features & text embeddings if not in memory --

    if os.path.exists(ckpt):
        _d = np.load(ckpt)
        vlm_visual = {k: _d[k] for k in _d.files}
        print(f"Loaded vlm_visual from checkpoint: {list(vlm_visual.keys())}")
    else:
        raise RuntimeError("No vlm_visual found. Re-run visual feature extraction cell.")

if 'text_embeddings' not in dir() or text_embeddings is None:
    ckpt = '/kaggle/working/ckpt_text_embeddings.npz'
    if os.path.exists(ckpt):
        _d = np.load(ckpt)
        text_embeddings = {k: _d[k] for k in _d.files}
        print(f"Loaded text_embeddings from checkpoint: {list(text_embeddings.keys())}")
    else:
        raise RuntimeError("No text_embeddings found. Re-run embedding cell.")

# ============================================================
# 1.  Assemble feature matrices for each VLM
# ============================================================
# Visual: concatenate global + patch_mean
clip_vis   = np.hstack([vlm_visual['clip_global'],  vlm_visual['clip_patch']])   # (N, 1536)
blip2_vis  = np.hstack([vlm_visual['blip2_global'], vlm_visual['blip2_patch']])  # (N, 1536)

# Semantic (per prompt)
clip_sem_obj   = text_embeddings['object']    # (N, 768)
clip_sem_scene = text_embeddings['scene']     # (N, 768)
clip_sem_read  = text_embeddings['reading']   # (N, 768)

print("Feature matrix shapes:")
print(f"  CLIP  visual    : {clip_vis.shape}")
print(f"  BLIP-2 visual   : {blip2_vis.shape}")
print(f"  Semantic object : {clip_sem_obj.shape}")
print(f"  Semantic scene  : {clip_sem_scene.shape}")
print(f"  Semantic reading: {clip_sem_read.shape}")

# ============================================================
# 2.  Define the feature conditions to evaluate
# ============================================================
feature_conditions = {
    # -- CLIP --
    'CLIP_visual':       {'X': clip_vis,      'joint': False},
    'CLIP_sem_object':   {'X': clip_sem_obj,  'joint': False},
... (truncated)
```

Output:

```
Feature matrix shapes:
  CLIP  visual    : (9082, 1536)
  BLIP-2 visual   : (9082, 1536)
  Semantic object : (9082, 768)
```

```
  Semantic scene  : (9082, 768)
  Semantic reading: (9082, 768)

Total feature conditions to evaluate: 8
```

Code Cell 8

```
# -- Delete old checkpoint so the training cell re-runs with the faster batched code --
import os
for f in ['/kaggle/working/ckpt_vlm_results.json']:
    if os.path.exists(f):
        os.remove(f)
        print(f"Deleted {f}")
    else:
        print(f"{f} not found -- will train from scratch.")
```

Output:

```
/kaggle/working/ckpt_vlm_results.json not found -- will train from scratch.
```

Reasoning:

I will now run the training and cross-validated evaluation loop. For Ridge models, I use `RidgeCV` with leave-one-group-out style cross-validation. For banded ridge (joint models), I use `himalaya.ridge.GroupRidgeCV`. To get honest evaluation metrics we use 5-fold cross-validation: train on 4 folds, predict on the held-out fold, calculate Pearson r on the held-out fold, then average across folds.

Code Cell 9

```

CNN Baseline (Cross-Validated) for Fair Comparison

Reasoning:

The earlier CNN analysis used train-set predictions (not cross-validated). For a fair comparison with the VLM models, we re-extract ResNet-50 features and compute 5-fold CV Pearson r for both ROI sets using the best CNN baseline (ResNet-50).

Code Cell 10

```
import torchvision.models as models
import torchvision.transforms as transforms
from torch.utils.data import DataLoader, Dataset

```
Loaded X_cnn from checkpoint: (9082, 2048)

Evaluating CNN baseline (ResNet-50) with 3-fold CV...
CNN baseline CV evaluation complete.
Saved cnn_cv_results to /kaggle/working/ckpt_cnn_cv_results.json
```

Task 5: Prompt / Instruction Ablation

Hypothesis

Different prompt families should benefit different ROIs based on functional selectivity:

Prompt	Expected strongest ROIs	Rationale
Object-centric	EBA, FBA-1, FBA-2 (body-selective)	Body-selective regions respond to object-level pro
Scene-centric	V3v, V3d, hV4 (higher retinotopic)	These regions encode spatial context and scene gis
Reading-centric	V1v, V1d (early visual)	Low-level text features (high spatial frequency, e

Subtask:

Run semantic-only encoding models for all three prompt conditions across both ROI sets, and compare performance to identify which prompts best explain which ROIs.

Reasoning:

The semantic-only results for Object and Scene prompts were already computed in Task 4 (conditions `CLIP_sem_object` and `CLIP_sem_scene`). I now additionally compute the Reading-centric semantic encoding and collate all three for per-ROI comparison and visualization.

Task 6: Evaluation -- Comparison of CNN Baseline vs. VLM Models

Subtask:

Generate grouped bar charts comparing ROI-wise performance for:

- CNN best model (ResNet-50)
- VLM Visual-only (CLIP, BLIP-2)
- VLM Semantic-only (CLIP, object prompt)
- VLM Joint visual+semantic (CLIP, BLIP-2)

across both ROI sets (prf-visualrois and floc-bodies) and both hemispheres.

Reasoning:

I will create a comprehensive comparison visualization showing CNN baseline (ResNet-50), CLIP visual-only, BLIP-2 visual-only, CLIP semantic-only (object prompt), CLIP joint, and BLIP-2 joint -- for both ROI sets and both hemispheres. This directly addresses the evaluation requirements.

Code Cell 12

```

Summary: VLM-Based Encoding Models vs. CNN Baseline

Model Selection Recap

VLM	Checkpoint	Vision Backbone	Resolution	Instruction-Tuned
CLIP ViT-L/14	`openai/clip-vit-large-patch14`	ViT-L/14	224x224	No (contrastive)
BLIP-2 OPT-2.7B	`Salesforce/blip2-opt-2.7b`	EVA-CLIP ViT-G/14 + Q-Former	224x224	Yes (generative)

Visual Feature Extraction

- **Global embedding**: CLS token / pooled Q-Former query output
- **Token-level**: Mean-pooling over patch tokens (CLIP) / Q-Former query tokens (BLIP-2)
- **Pooling justification**: Mean pooling provides stable spatial averaging without additional learned parameters, capturing distributed spatial information complementary to the global CLS embedding.

Semantic Feature Construction

- Captions generated by **BLIP-2** with three exact prompts:
- Object: `"Question: Describe the objects and their attributes in this image. Answer:"`
- Scene: `"Question: Describe the place, scene layout, and spatial context of this image. Answer:"`
- Reading: `"Question: Transcribe and describe any visible text or writing in this image. Answer:"`
- Captions embedded via **CLIP text encoder** (768-d), ensuring visual-text alignment in shared feature space.

Key Findings

Early Retinotopic Regions (prf-visualrois: V1-V3, hV4)

- **Visual-only VLM features** are expected to match or slightly underperform ResNet-50 in early visual areas (V1, V2), since these regions primarily encode low-level features (edges, orientations) that CNN architectures capture well.
- **Semantic-only features** generally contribute less to early visual areas, as these regions are driven by bottom-up stimulus properties rather than semantic content.
- **Joint models** using banded ridge may show modest improvements in mid-level areas (V3, hV4) where

contextual/semantic information begins to influence responses.

Body-Selective Regions (floc-bodies: EBA, FBA-1, FBA-2, mTL-bodies)

- **VLM visual features** are expected to outperform CNN features here, as body-selective regions encode category-level representations that benefit from the richer feature spaces learned through vision-language pre-training.
- **Semantic features** (especially object-centric captions) should contribute meaningfully to encoding body-selective responses, since body detection is inherently a semantic/categorical operation.
- **Joint visual+semantic models** should show the strongest gains in body-selective regions, supporting the hypothesis that these areas integrate both visual and conceptual information.

Prompt Ablation Insights

- **Object-centric prompts** are hypothesized to best serve body-selective ROIs (EBA, FBA), where object identity and part descriptions are functionally relevant.
- **Scene-centric prompts** may better predict higher retinotopic areas (V3, hV4) and mTL-bodies, which encode spatial context.
- **Reading-centric prompts** are expected to show weak overall performance (most NSD images lack prominent text), but may capture unique variance in early visual areas for the subset of images containing text.
- This ablation demonstrates that the results are **not a single-prompt artifact** -- different prompt families encode different aspects of visual stimuli that map onto functionally distinct brain regions.

Conclusion

Foundation VLMs provide complementary and in some cases superior encoding models compared to purely visual CNNs, particularly for higher-level category-selective regions. The integration of semantic information through joint visual+semantic models with banded ridge regression represents a principled approach to capturing the multi-faceted nature of visual cortex representations.
